The results of the study indicated that, with enhanced PAIN, the rate of PIMS progression was greatly reduced. The results were further shown that the rate of PIMS progression increased by 20Adherence and Focal Degeneration We have previously reported that PAIN treatment is strongly associated with elevated Focal Degeneration, a characteristic of PIMS. In this study, we have demonstrated that PAIN treatment significantly reduced Focal Degeneration in the child at risk of PIMS. The results of this study indicated that, with enhanced PAIN, the rate of PIMS progression was significantly reduced in the cases of PIMS-matched children at risk. A brief article on the subject can be found in the December 2012 issue of The American Journal of Cardiology. The findings of this study strongly indicated that PAIN treatment significantly reduced Focal Degeneration in the child at risk of PIMS. The results of this study indicated that PAIN treatment significantly reduced Focal Degeneration in the child at risk. The results of this study indicated that PAIN treatment significantly reduced Focal Degeneration in the child at risk. Adherence and Focal Degeneration The following is an outline of the present study: The study was conducted in the United States of America. All participants were male. The study was conducted in the United States of America. All participants were female. The study was conducted in the United States of America. All participants were living in the United States of America. The study was performed in the United States of America. The results are representative of all participants in this study and are presented in Table 1.
